## A wider framework

Networks and Geography in the economics of S\&T

## A wider framework

Networks and Geography in the economics of S\&T

## Networks and Geography

## Strategy I

Putting networks into geography

Relational vs. Spatial proximity

Strategies
Strategy II
Putting geography into networks

Object of analysis

Networks of "geographically-defined" meso/macro nodes

Space = Proximity
my behaviour = f(neighbours')
Who is my neighbour?

- Someone living nearby
- Someone I frequently interact with

Rationale of the analysis

Who establish and acts relations? Agents/organizations = micro level However micro behaviours are influenced by unobservable "local" conditions/interactions; thus the need for "meso/macro" analysis

Social Network Analysis
Spatial Econometrics:
Spatial + Relational weights

Analytical Tools

Social Network Analysis
Network Topology
Space = Distance -> Gravity models

## Aims of the presentation

Innovation activity is affected by spatial concentration at all geographical levels (Nuts2, Nuts3, TTWA, etc). Empirics shows that R\&D institutions (universities, govt.labs, H-T firms) do cluster

How do scientific information and knowledge flow between these clusters/regions?

- According to diffusive patterns based on spatial contiguity (unintended spatial spillover à la Acs, Anselin and Varga, 2002)?
- According to intentional relations based on a-spatial networks (knowledge barter exchange à la Cowan and Jonard, 1999)?

We analyse the information and knowledge flows associated with patents and co-patents in Europe (EU15: 171 NUTS2 regions) to:

- Measure the role of geography and relations
- Study the impact of EU S\&T policy (w.r.t. Framework programmes)

Relational networking: intentional knowledge barter exchange

## How to measure relational networking?

Through the EU 5 $5^{\text {th }}$ Framework Programme (1998-2002)
Aim of EU 5FP : "to integrate different research areas and to develop a critical mass of European resources in S\&T".
Total number of financed contracts: 16,085
We select contracts with a network structure (mainly joint research projects) and based our analysis on 6,755 networks between institutions ( $42 \%$ of total 5FP contracts): average membership being equal to 7 ( 6 participants +1 coordinator).
We aggregate these "institutional" networks at the regional level to:

- detect the unobservable structure of S\&T knowledge flows;
- compare geographic and relational autocorrelation phenomena;
- test the robustness of our previous results to enlarged sample of regions, different networks structures and link value patterns;
- study the effect of EU S\&T policy (Framework Programmes)

## Before the analysis: A logical guide to the presentation

In this paper we measure the effect of proximity on innovative performance (by spatial e'trix estimation techniques). Proximity (Maggioni et Al. 2007) has a Geographic and a Relational dimensions (2 dimensions: GEO, REL)
Since the actual relational structure measured by 5FP research networks is unobservable, we allow for different network structures (by limiting ourselves to "regular" patterns we identified 6 structures: A, B, C, D, E, F)
For each structure we allow also for different criteria for evaluation of links (5 links values: 1, N, L, FS, FA)
Econometric analysis is designed in order to detect which of the different specification of relational proximity is more relevant.
Ex-ante, 3 possible results:

- Results are robust to all specification = irrelevance of specification
- Results are significant and different for any specification = need for case studies a/o field experiments
- Results are significant only for a given specification = exact identification

A logical guide to the presentation Link values and direction

A logical guide to the presentation Link values and direction

Source:
Fagiolo et al. 2007

## A logical guide to the presentation Link values

For each structure we have to allow also for different criteria for evaluation of links (5 links values: 1, N, L, FS, FA). In other words we assume that each links is valued.
1 a constant value, irrespective of the number of nodes in the net
$\mathbf{N}$ a value which is inversely dependent on the number of nodes in the net
$L$ a value which is inversely dependent on the number of links in the net
FS the total funding of contract divided equally among participants
FA the total funding of contract divided unequally among participants
The coordinators gets
each participant gets
In a 5 nodes net, therefore each link may be alternatively valued:

## The weights matrices: spatial vs. relational

- Spatial weight matrix:

## Conclusion

This paper tests the joint role, within the innovation activity of European regions, of formal a-spatial networks between geographically distant region (intentional knowledge barter exchange) and diffusive patterns based on geographical contiguity (unintended knowledge spillovers).
Building on previous works we address two methodological issues:

- How to jointly estimates two different (GEO and REL) autocorrelation phenomena (weight matrix + lagged variable)
- How to model the unobservable structure and link value of actual knowledge flows within joint research project
Results show that:
- formal knowledge networks play a relevant role besides geographical spillovers;
- knowledge follows hierarchical structures (efficiency reasons?); therefore FP may sustain the "knowledge economy" but not regional cohesion if most coordinators are in core regions
- coordinating a large number of networks is not as important as being in the "right" networks (connected to other "hot spots")

## Future research

## After 10-15 years on knowledge-science-technology nets ...

- need to build a bridge between the "macro/descriptive" approach and the "micro-based" network formation/stability approach

## How can we achieve it?

- theoretical models which take into account more realistic hypotheses on the nature of knowledge and on the informational asymmetries, i.e. mix Jackson and Wolinsky (1996), with Cowan and Jonard (2004);
- behavioural experiments on how people thinks and acts when they have to establish relations in order to solve complex problems requiring collaboration (Callander and Plott, 2005);
- simulations of the same task performed by "rational, utility maximising agents/algorithm" (based on Maggioni, Uberti, 2009);
- field experiments (and case studies) based on specific Joint Research projects;
